## PROCESS FOR SELECTIVE DERIVATIZATION OF TAXANES

BACKGROUND OF THE INVENTION

The present invention is directed, in general, to a process for the preparation of taxol and other taxanes, and in particular, to such a process in which the C(7) or C(10) hydroxyl group of a taxane is selectively derivatized.

10-DAB (1), which is extracted from the needles of *taxus baccata* L., the English yew, has become a key starting material in the production of taxol and Taxotere, both of which are potent anticancer agents. Conversion of 10-DAB to taxol, Taxotere® and other taxanes having antitumor activity requires protection or derivatization of the C(7) and C(10) hydroxyl groups followed by esterification of the C(13) hydroxyl group to attach an appropriate side chain at that position.

- 1  $R_{10} = R_7 = H$   
 2  $R_{10} = H, R_7 = TES$

Until now, strategies for the preparation of taxol and taxol analogs were based upon the observation of Senilh et al. (C.R. Acad. Sci. Paris, II, 1981, 293, 501) that the relative reactivity of the four hydroxyl groups of 10-DAB toward acetic anhydride in pyridine is C(7)-OH > C(10)-OH > C(13)-OH > C(1)-OH. Denis, et. al. reported (J. Am. Chem. Soc., 1988, 110, 5917) selective silylation of the C(7) hydroxyl group of 10-DAB with triethylsilyl chloride in pyridine to give 7-triethylsilyl-10-deacetyl baccatin (III) (2) in 85% yield. Based upon these reports, in those processes in which differentiation of the C(7) and C(10) hydroxyl groups is required (e.g., preparation of taxol from 10-DAB), the C(7) hydroxyl group must be protected (or derivatized) before the C(10) hydroxyl group is protected or derivatized. For example, taxol may be prepared by treating 10-DAB with triethylsilyl chloride to protect the C(7) hydroxyl group, acetylating the C(10) hydroxyl group, attaching the side chain by esterification of the C(13) hydroxyl group, and, finally, removal of protecting groups.

It is known that taxanes having various substituents bonded to either the C(10) or the C(7) oxygens show anticancer activity. To provide for more efficient synthesis of these materials, it would be useful to have methods which permit more efficient and more highly selective protection or derivatization of the C(10) and the C(7) hydroxyl groups.

#### SUMMARY OF THE INVENTION

Among the objects of the present invention, therefore, is the provision of highly efficient processes for the preparation of taxol and other taxanes through selective derivatization of the C(7) group or the C(10) hydroxyl group of 10-DAB and other taxanes, particularly

a process in which the C(10) hydroxyl group is protected or derivatized prior to the C(7) hydroxyl group; and the provision of C(7) or C(10) derivatized taxanes.

Briefly, therefore, the present invention is directed to a process for the acylation of the C(10) hydroxy group of a taxane. The process comprises forming a reaction mixture containing the taxane and an acylating agent which contains less than one equivalent of a base for each equivalent of taxane, and allowing the taxane to react with the acylating agent to form a C(10) acylated taxane.

The present invention is further directed to a process for the silylation of the C(10) hydroxy group of a taxane having a C(10) hydroxy group. The process comprises treating the taxane with a silylamide or a bissilylamide to form a C(10) silylated taxane.

The present invention is further directed to a process for converting the C(7) hydroxy group of a 10-acyloxy-7-hydroxytaxane to an acetal or ketal. The process comprises treating the 10-acyloxy-7-hydroxytaxane with a ketalizing agent in the presence of an acid catalyst to form a C(10) ketalized taxane.

The present invention is further directed to a taxane having the structure:

wherein

M is a metal or comprises ammonium;

R<sub>1</sub> is hydrogen, hydroxy, protected hydroxy, or together with R<sub>14</sub> or R<sub>2</sub> forms a carbonate;

$R_2$  is keto,  $-OT_2$ , acyloxy, or together with  $R_1$  forms a carbonate;

$R_4$  is  $-OT_4$  or acyloxy;

$R_7$  is  $-OSiR_JR_KR_L$ ;

5  $R_9$  is hydrogen, keto,  $-OT_9$ , or acyloxy;

$R_{10}$  is hydrogen, keto,  $-OT_{10}$ , or acyloxy;

$R_{13}$  is hydroxy, protected hydroxy, keto, or  $MO-$ ;

$R_{14}$  is hydrogen,  $-OT_{14}$ , acyloxy, or together with  $R_1$  forms a carbonate;

10  $R_J$ ,  $R_K$ ,  $R_L$  are independently hydrocarbyl, substituted hydrocarbyl, or heteroaryl, provided, however, if each of  $R_J$ ,  $R_K$  and  $R_L$  are alkyl, at least one of  $R_J$ ,  $R_K$  and  $R_L$  comprises a carbon skeleton having at least four carbon atoms; and

15  $T_2$ ,  $T_4$ ,  $T_9$ ,  $T_{10}$ , and  $T_{14}$  are independently hydrogen or hydroxy protecting group.

Other objects and features of this invention will be in part apparent and in part pointed out hereinafter.

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

20 Among other things, the present invention enables the selective derivatization of the C(10) hydroxyl group of a taxane without first protecting the C(7) hydroxyl group. Stated another way, it has been discovered that the reactivities previously reported for the C(7) and  
25 C(10) hydroxyl groups can be reversed, that is, the reactivity of the C(10) hydroxyl group becomes greater than the reactivity of the C(7) hydroxyl group under certain conditions.

30 Although the present invention may be used to selectively derivatize a taxane having a hydroxy group at C(7) or C(10), it offers particular advantages in the selective derivatization of taxanes having hydroxy groups

5

at C(7) and C(10), i.e., 7,10-dihydroxy taxanes. In general, 7,10-dihydroxytaxanes which may be selectively derivatized in accordance with the present invention correspond to the following structure:

$R_4$  is  $-OT_4$  or acyloxy;

$R_9$  is hydrogen, keto,  $-OT_9$ , or acyloxy;

$R_{13}$  is hydroxy, protected hydroxy, keto, or

15

$R_{14}$  is hydrogen,  $-OT_{14}$ , acyloxy or together with  $R_1$  forms a carbonate;

$T_2$ ,  $T_4$ ,  $T_9$ , and  $T_{14}$  are independently hydrogen or hydroxy protecting group;

20  $X_1$  is  $-OX_6$ ,  $-SX_7$ , or  $-NX_8X_9$ ;

$X_2$  is hydrogen, hydrocarbyl, substituted hydrocarbyl, or heteroaryl;

$X_3$  and  $X_4$  are independently hydrogen, hydrocarbyl, substituted hydrocarbyl, or heteroaryl;

$X_{11}$  is hydrocarbyl, substituted hydrocarbyl, heteroaryl,  $-OX_{10}$ , or  $-NX_8X_{14}$ ; and

$X_{14}$  is hydrogen, hydrocarbyl, substituted  
15       hydrocarbyl, or heteroaryl.

#### Selective C(10) Derivatization

In accordance with the process of the present invention, it has been discovered that the C(10) hydroxyl group of a taxane can be selectively acylated in the  
20       absence of a base, preferably in the absence of an amine base. Preferably, therefore, amine bases such as pyridine, triethylamine, dimethylaminopyridine and 2,6-lutidine, if present at all, are present in the reaction mixture in relatively low concentration. Stated another  
25       way, if a base is present in the reaction mixture, the molar ratio of the amine base to the taxane is preferably less than 1:1, more preferably less than 10:1, and most preferably less than 100:1.

Acylating agents which may be used for the selective  
30       acylation of the C(10) hydroxyl group of a taxane include anhydrides, dicarbonates, thiodicarbonates, and isocyanates. In general, the anhydrides, dicarbonates, and thiodicarbonates correspond to structure 4 and the isocyanates correspond to structure 5:

wherein  $\text{R}^1$  is  $-\text{OR}^a$ ,  $-\text{SR}^a$ , or  $\text{R}^a$ ;  $\text{R}^2$  is  $-\text{OC}(\text{O})\text{R}^b$ ,  $-\text{OC}(\text{O})\text{OR}^b$ ,  $-\text{OC}(\text{O})\text{SR}^b$ ,  $-\text{OPOR}^b\text{R}^c$ , or  $-\text{OS}(\text{O})_2\text{R}^b$ ;  $\text{R}^3$  is hydrocarbyl, substituted hydrocarbyl, or heteroaryl; and  $\text{R}^a$ ,  $\text{R}^b$ ,  $\text{R}^c$  are independently hydrocarbyl, substituted hydrocarbyl, or heteroaryl. For example, suitable carboxylic acid anhydride acylating agents include acetic anhydride, chloroacetic anhydride, propionic anhydride, benzoic anhydride, and other carboxylic acid anhydrides containing substituted or unsubstituted hydrocarbyl or heteroaryl moieties; suitable dicarbonate acylating reagents include dibenzyl dicarbonate, diallyl dicarbonate, dipropyl dicarbonate, and other dicarbonates containing substituted or unsubstituted hydrocarbyl or heteroaryl moieties; and suitable isocyanate acylating agents include phenyl isocyanate, and other isocyanates containing substituted or unsubstituted hydrocarbyl or heteroaryl moieties. In addition, although the anhydrides, dicarbonates, and thiodicarbonates used as acylating agents may be mixed, it is generally preferred that they be symmetrical; that is,  $\text{R}^1$  and  $\text{R}^2$  are selected such that the molecule is symmetrical (e.g., if  $\text{R}^1$  is  $\text{R}^a$ ,  $\text{R}^2$  is  $-\text{OC}(\text{O})\text{R}^b$  with  $\text{R}^a$  being the same as  $\text{R}^b$ ).

While the acylation of the C(10) hydroxy group of the taxane will proceed at an adequate rate for many acylating agents, it has been discovered that the reaction rate may be increased by including a Lewis acid in the reaction mixture. The concentration of the Lewis acid appears not to be narrowly critical; experimental evidence obtained to date suggests it may be present in either a stoichiometric or a catalytic amount. In general, Lewis acids which may be used include triflates and halides of elements of groups IB, IIB, IIIB, IVB, VB,

VIB, VIIB, VIII, IIIA, IVA, lanthanides, and actinides of the Periodic Table (American Chemical Society format).

Preferred Lewis acids include zinc chloride, stannic chloride, cerium trichloride, cuprous chloride, lanthanum trichloride, dysprosium trichloride, and ytterbium trichloride. Zinc chloride or cerium trichloride is particularly preferred when the acylating agent is an anhydride or dicarbonate. Cuprous chloride is particularly preferred when the acylating agent is an isocyanate.

The solvent for the selective acylation is preferably an ethereal solvent such as tetrahydrofuran. Alternatively, however, other solvents such as ether or dimethoxyethane may be used.

The temperature at which the C(10) selective acylation is carried out is not narrowly critical. In general, however, it is preferably carried out at room temperature or higher in order for the reaction to proceed at a sufficiently high rate.

For purposes of illustration, acylating reactions involving dibenzyl dicarbonate, diallyl dicarbonate, acetic anhydride, chloroacetic anhydride and phenyl isocyanate are illustrated in Reaction Schemes 1 through 5 below. In this series of reaction schemes, the taxane which is selectively acylated at the C(10) position is 10-deacetylbaccatin III. It should be understood, however, that these reaction schemes are merely illustrative and that other taxanes having a C(10) hydroxy group, in general, and other 7,10-dihydroxytaxanes, in particular, may be selectively acylated with these and other acylating agents in accordance with the present invention.

Scheme 1Scheme 25 Scheme 3

Scheme 4Scheme 5

- 5 In another aspect of the present invention, the C(10) hydroxyl group of a taxane may be selectively silylated. In general, the silylating agent is selected from the group consisting of silylamides and bissilylamides. Preferred silylamides and bissilyamides
- 10 correspond to structures 6 and 7, respectively:

- wherein  $\text{R}_D$ ,  $\text{R}_E$ ,  $\text{R}_F$ ,  $\text{R}_G$ , and  $\text{R}_H$  are independently hydrocarbyl, substituted hydrocarbyl, or heteroaryl.
- 15 Preferably, the silylating agents are selected from the group consisting of tri(hydrocarbyl)silyl-trifluoromethylacetamides and bis tri(hydrocarbyl)-

silyltrifluoromethylacetamides, with the hydrocarbyl moiety being substituted or unsubstituted alkyl or aryl. For example, the preferred silylamides and bissilylamides include N,O-bis-(trimethylsilyl) trifluoroacetamide, N,O-bis-(triethylsilyl)trifluoroacetamide, N-methyl-N-triethylsilyltrifluoroacetamide, and N,O-bis(t-butyldimethylsilyl)trifluoroacetamide.

The silylating agents may be used either alone or in combination with a catalytic amount of a base such as an alkali metal base. Alkali metal amides, such as lithium amide catalysts, in general, and lithium hexamethyldisilazide, in particular, are preferred.

The solvent for the selective silylation reaction is preferably an ethereal solvent such as tetrahydrofuran. Alternatively, however, other solvents such as ether or dimethoxyethane may be used.

The temperature at which the C(10) selective silylation is carried out is not narrowly critical. In general, however, it is carried out at 0 °C or greater.

Selective C(10) silylation reactions involving N,O-bis(trimethylsilyl)trifluoroacetamide and N,O-bis(triethylsilyl)trifluoroacetamide are illustrated in Reaction Schemes 6 and 7 below. In these reaction schemes, the taxane which is selectively silylated at the C(10) position is 10-deacetylbaccatin III. It should be understood, however, that these reaction schemes are merely illustrative and that other taxanes, having a C(10) hydroxy group, in general, and other 7,10-dihydroxytaxanes, in particular, may be selectively silylated with these and other silylating agents in accordance with the present invention.

Scheme 6Scheme 7

- 5            After the C(10) hydroxyl group of a  
 7,10-dihydroxytaxane has been derivatized as described  
 herein, the C(7) hydroxyl group can readily be protected  
 or otherwise derivatized selectively in the presence of  
 the C(1) and C(13) hydroxyl groups (and a C(14) hydroxy  
 10 group, if present).

Selective C(7) Derivatization

- 15           Selective acylation of the C(7) hydroxyl group of a  
 C(10) acylated or silylated taxane can be achieved using  
 any of a variety of common acylating agents including,  
 but not limited to, substituted and unsubstituted  
 carboxylic acid derivatives, e.g., carboxylic acid  
 halides, anhydrides, dicarbonates, isocyanates and  
 haloformates. For example, the C(7) hydroxyl group of  
 baccatin III, 10-acyl-10-deacetyl baccatin III or

10-triethylsilyl-10-deacetyl baccatin III can be selectively acylated with dibenzyl dicarbonate, diallyl dicarbonate, 2,2,2-trichloroethyl chloroformate, benzyl chloroformate or another common acylating agent.

5 In general, acylation of the C(7) hydroxy group of a C(10) acylated or silylated taxane are more efficient and more selective than are C(7) acylations of a 7,10-dihydroxy taxane such as 10-DAB, i.e., once the C(10) hydroxyl group has been acylated or silylated, there is a  
10 significant difference in the reactivity of the remaining C(7), C(13), and C(1) hydroxyl groups (and the C(14) hydroxyl group, if present). These acylation reactions may optionally be carried out in the presence or absence of a base.

15 Examples of selective C(7) acylation of a taxane having an acylated or silylated C(10) hydroxy group are shown in Reaction Schemes 8 through 11. In these reaction schemes, the taxane which is selectively acylated at the C(7) position is baccatin III or  
20 10-triethylsilyl-10-deacetyl baccatin III. It should be understood, however, that these reaction schemes are merely illustrative and that taxanes having other acyl and silyl moieties at C(10) as well as other substituents at other taxane ring positions may be selectively  
25 acylated at C(7) with these and other acylating agents in accordance with the present invention.

Scheme 8

Scheme 9Scheme 105 Scheme 11

Alternatively, the C(7) hydroxyl group of a C(10) acylated taxane derivative can be selectively protected using any of a variety of hydroxy protecting groups, such as acetal, ketal, silyl, and removable acyl protecting groups. For example, the C(7) hydroxyl group may be silylated using any of a variety of common silylating agents including, but not limited to,

tri(hydrocarbyl)silyl halides and tri(hydrocarbyl)silyl triflates. The hydrocarbyl moieties of these compounds may be substituted or unsubstituted and preferably are substituted or unsubstituted alkyl or aryl. For example, the C(7) hydroxyl group of baccatin III can be selectively silylated using silylating agents such as tribenzylsilyl chloride, trimethylsilyl chloride, triethylsilyl chloride, dimethyl isopropylsilyl chloride, dimethyl phenylsilyl chloride, and the like.

10 In general, silylations of the C(7) hydroxy group of a C(10) acylated taxanes are more efficient and more selective than are silylations of a 7,10-dihydroxy taxane such as 10-DAB, i.e., once the C(10) hydroxyl group has been acylated, there is a significant difference in the reactivity of the remaining C(7), C(13), and C(1) hydroxyl groups (and the C(14) hydroxyl group, if present). The C(7) silylation reaction may be carried out under a wide range of conditions, including in the presence or absence of an amine base.

20 Examples of selective C(7) silylation of C(10) acylated taxanes are shown in Reaction Schemes 12 through 15. In these reaction schemes, the taxane which is selectively silylated at the C(7) position is baccatin III or another C(10)-acyloxy derivative of 10-deacetyl baccatin III. It should be understood, however, that these reaction schemes are merely illustrative and that other taxanes may be selectively silylated with these and other silylating agents in accordance with the present invention.

Scheme 12Scheme 135 Scheme 14

Scheme 15

Alternatively, the C(7) hydroxyl group of C(10) acylated taxanes can be selectively protected using any of a variety of common reagents including, but not limited to, simple acetals, ketals and vinyl ethers, in the presence of an acid catalyst. These reagents (whether acetal, ketal, vinyl ether or otherwise) are referred to herein as "ketalizing agents" and are described in "Protective Groups in Organic Synthesis" by T. W. Greene, John Wiley and Sons, 1981. The acid catalyst used may be an organic or inorganic acid, such as toluenesulfonic acid or camphorsulfonic acid, in at least a catalytic amount. For example, the C(7) hydroxyl group of baccatin III can be selectively ketalized using 2-methoxy propene. Other suitable reagents for the preparation of acetals and ketals include methyl vinyl ether, ethyl vinyl ether, tetrahydropyran, and the like.

Selective ketalization of the C(7) substituent of a C(10) acylated taxane is more efficient and more selective than it is with 10-DAB; i.e., once the C(10) hydroxyl group has been acylated, there is a large difference in the reactivity of the remaining C(7), C(13), and C(1) hydroxyl groups (and the C(14) hydroxyl group, if present).

An example of selective formation of a C(7) ketal from baccatin III is illustrated in Reaction Scheme 16. It should be understood, however, that this reaction

scheme is merely illustrative and that other taxanes may be selectively ketalized with this and other ketalizing agents in accordance with the present invention.

Scheme 16

Under appropriate conditions, the C(7) hydroxyl group of a taxane further comprising a C(10) hydroxyl group can be selectively silylated. Advantageously, these silylations are not limited to silyl groups bearing alkyl substituents having three carbons or less.

In general, the C(7) hydroxyl group of a taxane can be selectively silylated with a silylating agent which includes the  $-\text{SiR}_j\text{R}_k\text{R}_l$  moiety wherein  $\text{R}_j$ ,  $\text{R}_k$  and  $\text{R}_l$  are independently substituted or unsubstituted hydrocarbyl or heteroaryl, provided that any substituents are other than hydroxyl. In one embodiment of the present invention, if each of  $\text{R}_j$ ,  $\text{R}_k$  and  $\text{R}_l$  is alkyl, then at least one of  $\text{R}_j$ ,  $\text{R}_k$ , and  $\text{R}_l$  comprises a carbon skeleton (i.e., carbon chain or ring(s)) having at least four carbon atoms. Suitable silylating agents include silyl halides and silyl triflates, for example, tri(hydrocarbyl)silyl halides and tri(hydrocarbyl)silyl triflates. The hydrocarbyl substituents of these silylating agents may be substituted or unsubstituted and preferably are substituted or unsubstituted alkyl or aryl.

The selective silylation of the C(7) hydroxy group may be carried out in a solvent, such as dimethylformamide ("DMF") or pyridine and in the presence of an amine base, such as imidazole or pyridine. Reaction Schemes 17 - 20 illustrate the silylation of the C(7) hydroxy group of 10-DAB in high yield by treating 10-DAB with t-butyldimethylsilyl chloride, tribenzylsilyl chloride, dimethyl-isopropylsilyl chloride, and dimethylphenylsilyl chloride, respectively. Silylation under these conditions was surprising in view of the report by Denis, et. al. (*J. Am. Chem. Soc.*, 1988, 110, 5917) that selective formation of 7-TBS-10-DAB was not possible.

Scheme 17Scheme 18

Scheme 19Scheme 20

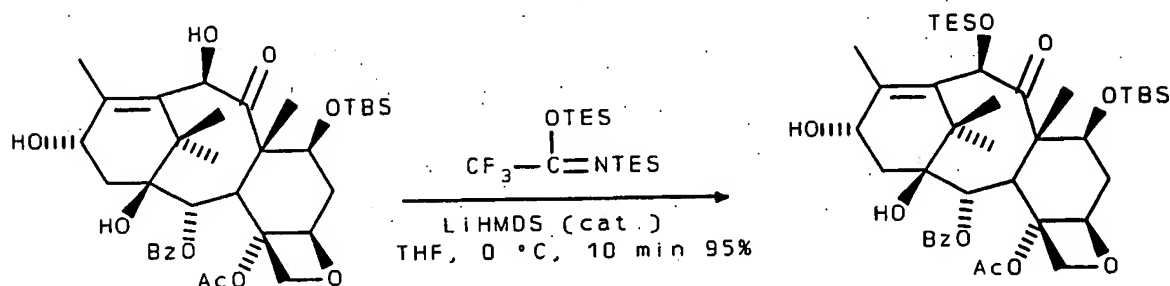

5        The process of the present invention can also be used to protect the C(7) and C(10) hydroxy groups of a 7,10-dihydroxytaxane with different silyl protecting groups. By selecting groups which can be removed under different conditions, the C(7) and C(10) hydroxy groups

10       can be separately accessed for derivatization. These reactions, therefore, increase the flexibility of the overall process and, enable a higher yield for many of the individual protecting reactions relative to the yield obtained using currently available processes. For

15       example, the triethylsilyl protecting group is more readily removed from C(10) than is the t-butyldimethylsilyl protecting group from C(7) and the dimethylphenylsilyl protecting group is more readily removed from C(7) than is the t-butyldimethylsilyl

protecting group from C(10). The preparation of 7-t-butyldimethylsilyl-10-triethylsilyl-10-DAB and 7-dimethylphenylsilyl-10-t-butyldimethylsilyl-10-DAB are illustrated in Reaction Schemes 21 and 22.

### 5 Scheme 21

### Scheme 22

The methods disclosed herein may be used in connection with a large number of different taxanes obtained from natural or synthetic sources to prepare a wide variety of taxane intermediates which may then be further derivatized. For example, the methods of the present invention may be effectively used to protect the C(7) and/or C(10) hydroxy functional group prior to the coupling reaction between a C(13) side chain precursor and a taxane to introduce a C(13)  $\beta$ -amido ester side chain, and also prior to the reactions for preparing taxanes having alternative substituents at various locations on the taxane nucleus.

The attachment of a C(13) side chain precursor to a taxane may be carried out by various known techniques. For example, a side chain precursor such as an appropriately substituted  $\beta$ -lactam, oxazoline, oxazolidine carboxylic acid, oxazolidine carboxylic acid anhydride, or isoserine derivative may be reacted with a tricyclic or tetracyclic taxane having a C(13) hydroxy, metallic oxide or ammonium oxide substituent to form compounds having a  $\beta$ -amido ester substituent at C(13) as described, for example, Taxol: Science and Applications, M. Suffness, editor, CRC Press (Boca Rotan, FL) 1995, Chapter V, pages 97-121. For example, the synthesis of taxol from 10-DAB is illustrated in reaction scheme 23. It should be noted that while a  $\beta$ -lactam and 10-DAB are used in this reaction scheme, other side chain precursors and other taxanes could be substituted therefor without departing from the present invention.

Scheme 23

The process illustrated in Reaction Scheme 23 is significantly more efficient than any other currently known process, due to the high yields and selectivity of the cerium trichloride catalyzed acetylation of the C(10) hydroxyl group of 10-DAB and the subsequent silylation of the C(7) hydroxyl group. The synthesis proceeds in four steps and 89% overall yield.

Reaction schemes 24 and 25 illustrate the preparation of taxanes having substituents appended to the C(7) hydroxyl group and a free C(10) hydroxyl group. The method of the current invention provides flexibility so that the substituent attached to the C(7) hydroxyl group can be put in place either before or after attachment of the C(13) side chain.

Reaction scheme 24 outlines the preparation of a taxane which has been found to be a potent chemotherapeutic radiosensitizer, illustrating attachment of the substituent at the C(7) hydroxyl group before introduction of the C(13) side chain. According to the process of reaction scheme 7, 10-DAB is first converted to 10-TES-10-DAB. The C(7) hydroxyl group is then converted to an intermediate imidazolidine by treatment with carbonyl diimidazole, and the intermediate imidazolidine subsequently reacts, without isolation, with metronidazole alcohol to provide 7-metro-10-TES-10-DAB. Coupling of 7-metro-10-TES-10-DAB with a  $\beta$ -lactam to introduce the side chain at C(13) is followed by removal of the TES groups at C(10) and C(2') by treatment with HF and pyridine.

Scheme 24

Reaction scheme 25 outlines the preparation of a taxane useful in identifying proteins which form bioconjugates with taxanes. It illustrates a protocol for attachment of a substituent at the C(7) hydroxyl group after introduction of the C(13) side chain.

5 According to the processes of reaction schemes 7 and 11, 10-DAB is first converted to 7-p-nitrobenzyloxycarbonyl-10-TES-10-DAB. The C(13) side chain is attached employing a TES protected  $\beta$ -lactam, and the

10 p-nitrobenzyloxycarbonyl protecting group is then selectively removed by treatment with hydrogen and a palladium catalyst, producing 2',10-(bis)-TES-taxotere. The C(7) hydroxyl group then reacts with carbonyl

15 1,4-diamino butane to give a primary amine. Reaction of the primary amine with the hydroxysuccinimide ester of biotin completes the attachment of the biotinamide group at C(7). Finally, treatment with HF in pyridine solution removes the TES protecting groups at C(10) and C(2').

Scheme 25

The protected taxane derivatives or the intermediates or starting materials used in the preparation of such protected taxane derivatives can be further modified to provide for alternative substituents at various positions of the taxane.

Taxanes having C(2) and/or C(4) substituents other than benzyloxy and acetoxy, respectively, can be prepared from baccatin III, 10-DAB and other taxanes as more fully described in PCT Patent Application WO 94/01223. In general, the C(2) and C(4) acyloxy substituents are treated with lithium aluminum hydride or another suitable reducing agent to form hydroxy groups at C(2) and C(4) which may then be reacted, for example, with carboxylic acid halides (optionally after protection of the C(2) hydroxy group together with the C(1) hydroxy group with a 1,2-carbonate protecting group) to obtain the desired C(2) and C(4) derivatives.

Taxanes having C(7) substituents other than hydroxy and acyloxy as described herein can be prepared from baccatin III, 10-DAB, and other taxanes as more fully described in PCT Patent Application WO 94/17050. For example, a C(7) xanthate may be subjected to tin hydride reduction to yield the corresponding C(7) dihydro taxane. Alternatively, C(7) fluoro-substituted taxanes can be prepared by treatment of C(13)-triethylsilyl-protected baccatin III with 2-chloro-1,1,2-trifluoroethylamine at room temperature in THF solution. Other baccatin derivatives with a free C(7) hydroxyl group behave similarly. Alternatively, 7-chloro baccatin III can be prepared by treatment of baccatin III with methanesulfonyl chloride and triethylamine in methylene chloride solution containing an excess of triethylamine hydrochloride.

Taxanes having C(9) substituents other than keto can be prepared from baccatin III, 10-DAB and other taxanes as more fully described in PCT Patent Application WO

94/20088. In general, the C(9) keto substituent of the taxane is selectively reduced to yield the corresponding C(9)  $\beta$ -hydroxy derivative with a borohydride, preferably tetrabutylammonium borohydride ( $\text{Bu}_4\text{NBH}_4$ ) or triacetoxy-borohydride. The C(9)  $\beta$ -hydroxy derivative can then be protected at C(7) with a hydroxy protecting group and the C(9) hydroxy group can be acylated following the methods described herein for acylation of the C(7) hydroxy group. Alternatively, reaction of 7-protected-9 $\beta$ -hydroxy derivative with KH causes the acetate group (or other acyloxy group) to migrate from C(10) to C(9) and the hydroxy group to migrate from C(9) to C(10), thereby yielding a 10-desacetyl derivative, which can be acylated as described elsewhere herein.

Taxanes having C(10) substituents other than hydroxy, acyloxy or protected hydroxy as described herein may be prepared as more fully described in PCT Patent Application WO 94/15599 and other literature references. For example, taxanes having a C(10) keto substituent can be prepared by oxidation of 10-desacetyl taxanes. Taxanes which are dihydro substituted at C(10) can be prepared by reacting a C(10) hydroxy or acyloxy substituted taxane with samarium diiodide.

Taxanes having a C(14) substituent other than hydrogen may also be prepared. The starting material for these compounds may be, for example, a hydroxylated taxane (14-hydroxy-10-deacetylbaaccatin III) which has been discovered in an extract of yew needles (C&EN, p 36-37, April 12, 1993). Derivatives of this hydroxylated taxane having the various C(2), C(4), C(7), C(9), C(10), C3' and C5' functional groups described above may also be prepared by using this hydroxylated taxane. In addition, the C(14) hydroxy group together with the C(1) hydroxy group of 10-DAB can be converted to a 1,2-carbonate as

described in C&EN or it may be converted to a variety of esters or other functional groups as otherwise described herein in connection with the C(2), C(4), C(9) and C(10) substituents.

20 C. Selective acylation of a C(10) hydroxyl group using  
 CeCl<sub>3</sub>:

General procedure: To a solution of 10-DAB in THF  
 (20 mL per mmol of 10-DAB) under N<sub>2</sub> was added CeCl<sub>3</sub> and  
 the appropriate anhydride or pyrocarbonate (amounts  
 specified in Table 1). The reaction mixture was stirred  
 25 at 25 °C and monitored by TLC analysis. When that  
 analysis indicated complete reaction (time specified in  
 Table 1), the reaction mixture was diluted with EtOAc and  
 washed three times with saturated aqueous sodium  
 bicarbonate solution. The combined bicarbonate washings  
 30 were extracted three times with EtOAc, the organic layers  
 were combined and dried over sodium sulfate, and the  
 solvent was evaporated. The crude product was purified  
 by flash column chromatography. Further purification, if  
 necessary, was carried out by recrystallization from  
 35 EtOAc/Hexane.

#### D. Selective carbamoylation of a C(10) hydroxyl group:

General procedure for the Selective Carbamoylation of the C-10 Hydroxyl group of 10-DAB: A solution of 0.061 mmol (1.1 mol equiv) of the isocyanate in 2 mL of THF was added, under nitrogen, to a mixture of 10-DAB (30 mg, 0.055 mmol) and CuCl (5.5 mg, 0.055 mmol) at 0 °C. The mixture was stirred for the time indicated in Table 2. After this time the reaction was warmed to 25 °C and stirring was continued for the time indicated in Table 2. The reaction was quenched by the addition of saturated aqueous ammonium chloride solution, and the mixture was extracted three times with EtOAc. The combined organic

layers were washed with saturated aqueous  $\text{NaHCO}_3$  solution, dried over sodium sulfate, and the solvent was evaporated to yield a white solid. The product was purified by flash column chromatography using 2:1 EtOAc/hexane as the eluent.

*Selective Esterification of the C-10 Hydroxyl of*  
*10-DAB using the catalytic DyCl<sub>3</sub> reaction:* A solution of  
 butyric anhydride (0.55 mmol) in THF (1.32 ml) was added,  
 under a nitrogen atmosphere, to a solid mixture of 10-DAB  
 25 (30 mg, 0.055 mmol) and DyCl<sub>3</sub> (1.3 mg, 10 mol.% wrt  
 10-DAB). The resulting suspension was stirred at room  
 temperature until judged complete by TLC (2:1  
 EtOAc/Hexane). The reaction was diluted with EtOAc and  
 washed three times with saturated NaHCO<sub>3</sub> solution. The  
 30 combined bicarbonate washings were extracted three times  
 with EtOAc, these combined organics were dried (Na<sub>2</sub>SO<sub>4</sub>)  
 and the solvent evaporated. The crude product was  
 triturated with hexanes and the mother liquors decanted

away. Crystallization from EtOAc/hexanes yielded 10-butyl-10-DAB identical to that isolated from the  $\text{CeCl}_3$  catalysed reaction.
